Foreword

This Demographic Yearbook in tabular form presents the main statistical indicators reflecting the demographic processes of Kazakhstan and its regions for 2020-2024.

The compilation contains statistical data on the change in the total number and age and gender composition of the population, birth and death rates, marriage and divorce rates, migration, life expectancy, and the administrative-territorial division.

Агентство по стратегическому планированию и реформам Республики Казахстан|АНаурзбекова А. Б.

Content

1. Main demographic indicators.....6
2. Territory and administrative division 7
3. Size and composition of the population 11
4. Vital statistics 64
5. Marriages and divorces 76
6. Fertility rates 89
7. Mortality rates 149
8. Life expectancy 247
9. Migration 249
Methodological notes 267

Methodological notes

Information on the administrative-territorial division is based on official materials received from the executive bodies of Kazakhstan.

Territory size - a statistical indicator characterizing the area occupied by the state as a whole and its regions, measured in square kilometers. The sizes of the territories are given according to the Committee on Land Management of the Ministry of Agriculture of the Republic of Kazakhstan. The population density indicator is calculated as the ratio of the population to the area of the territory.

The population, the number of people living in the area at a given time.

The current estimates at the beginning of the year are calculated based on the results of the last census of the population, to which the number of births and arrivals for the permanent place of residence in a given area are added annually and the numbers of those who died and left for the permanent place of residence are subtracted from the territory. Current estimates of the population over the past years are updated on the basis of the results of the next census.

Estimates of population are made for the whole of Kazakhstan and its individual administrative-territorial units (urban settlements, urban districts, administrative districts). The calculations take into account the increase or decrease in the population of individual territories as a result of changes in their boundaries, as well as changes in the number of urban and rural population as a result of administrative and territorial changes.

The population is divided into urban and rural population. Urban population - population living in urban settlements. Urban settlements include cities of republican, regional and district significance, as well as towns located in the territory of their administrative subordination. Rural population - the population living in rural areas. Human settlements that are not classified as urban are considered to be rural.

Natural increase is the difference between the number of live births and the number of deaths over a certain period. Natural increase can be a positive value if the number of births exceeds the number of deaths, or negative (natural decline) - otherwise.

Net migration is the difference between the number of arrivals for a certain period in a given territory and the number of departures beyond its borders. Net migration can be positive (if the number of arrivals is greater than the number of departures), or negative (if the number of arrivals is less than the number of departures). In the latter case there is a migration outflow.

The calculation of the age and sex composition of the population at the beginning of each calendar year is made after the completion of the calculation of the total population.

Indicators of population structure by age and sex are the most important characteristic of the population. For clarity, they are presented in the form of age-sex pyramid. When a graphic image of the age-sex pyramid along the vertical axis, their share in the total population, age or year of birth, is deposited horizontally - the number of people of each age is to the left from the axis - Male, to the right - Female.

The crude birth rate is an indicator that determines the intensity of childbearing in relation to the entire population. It represents the ratio of the total number of live births during the year to the mid-year population. It is usually calculated per 1000 population.

The crude death rate is an indicator that determines the intensity of mortality of a population. It represents the ratio of the total number of deaths during the year to the mid-year population. It is usually calculated per 1000 population.

Natural increase rate is the difference in crude birth and death rates.

Life expectancy at birth is the number of years that, on average, one person from the generation of births would have to live, provided that throughout this generation the mortality rate at each age remains the same as in the year for which the indicator is calculated.

Information on marriages and divorces (dissolved marriages) is based on the annual statistical processing of the data contained in the acts of civil status compiled for each such event by the Civil registration authorities, as well as by the decision of the courts on the dissolution of marriage. The data in the tables cover only cases of marriages registered by the Civil registration authorities.

The age of marriage is calculated as the time interval between the date of registration of marriage and the date of birth.

The date of marriage is the date of its registration with the RAGS. A marriage is considered terminated from the time of registration of its termination (from the moment of divorce). The age of divorces is calculated as the time interval between the date of registration of the divorce and the date of birth. Duration of divorce is calculated as the time interval between the dates of termination and marriage.

The crude marriage and divorce rates are calculated as the ratio of the number of marriages concluded and divorced during the calendar year to the mid-year population, respectively.

Information on births is based on the annual statistical development of data contained in birth certificates complied by the RAGS and medical birth certificates, on the basis of which birth certificates are complied. Only those born alive are included in the number of births.

Live birth is the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of the pregnancy, which, after such separation, breathes or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached.

Birth registration is made at the place of birth of the child or at the place of residence of the parents (or one of them) on the basis of a medical birth certificate issued by a maternity hospital or hospital establishing the fact and time of birth of the child. Statistics on births are generated by the place of residence of the mother of the child.

A child born dead is registered as born, but with a stillbirth mark on the basis of a medical certificate of perinatal death. If the death of a child occurred soon after his birth, then two entries are made: about birth and about death.

Those who were born alive to women who were not in a registered marriage include births, upon registration of which information about the father is indicated in the record of the child's birth certificate on the basis of a joint statement of the father and mother, or a statement only from the mother, or a court decision establishing paternity, which is noted in the record The birth certificate is

Агентство по статистике Республики Казахстан

marked accordingly.

Reproductive period (age) - the period of time during which a woman is capable of childbirth. For statistical purposes, in most countries a period of 15–49 years is assumed.

Age-specific fertility rates are the annual number of births to women in each age group per 1000 . When calculating fertility rate for the age group up to 20 years, the number of women aged 15-19 years is taken as the denominator. When calculating fertility rate for the age group of 15-49 years, the numerator includes all births, including those born to mothers aged as young as 15, and 50 years and older.

Information on deaths is based on the annual statistical development of data contained in death certificates complied by the RAGS authorities and medical death certificates, on the basis of which death certificates are complied.

Registration of death is made at the place where the deceased lived or at the place of death. Statistical data on deaths in the regions of the Republic of Kazakhstan are compiled by the permanent place of residence of the deceased.

Age-specific death rates are calculated as the ratio of the number of deaths at a given age during a calendar year to the average annual number of people of that age. Similarly, death rates by causes of death are calculated as the ratio of the numbers of deaths from the specified causes of death to the mid-year population.

The infant mortality rate is an indicator that determines the mortality rate of children under one year of age. Calculated by the ratio of the number of deaths under the age of 1 year to the number of live births. Since children born in the previous calendar year may also include babies who died in a given calendar year, the infant mortality rate in a given calendar year is calculated for the generation born in this and previous calendar years.

Migration of the population - the movement of people (migrants) across the borders of certain regions with a change of residence. The number of people arriving and departing is determined as a result of the development of information on the registration of the population for permanent residence received from the Ministry of Internal Affairs of the Republic of Kazalhstan.

In the current statistical accounting, the numbers of arrivals and departures are conventionally recorded, but in reality, it is a question of the numbers of arrivals and departures.

The main indicators of migration are:

number of arrivals;

number of departure;

net migration.

Indicators of the intensity of migration characterize the frequency of cases of relocation in the population for a certain period. More often uses the annual migration intensity per 1000 population.
